ABSTRACT
Interaction-Oriented Programming (IOP) is an approach for engineering decentralized multiagent systems based in the idea of modeling interaction meaning. Modeling meaning enables agents to make flexible decentralized decisions. IOP addresses the key architectural elements of multiagent systems, from communication services for messaging to protocols and norms. In this demo, we showcase the tools developed over the last decade that enable specifying, verifying, and implementing meaning-based, decentralized multiagent systems.

KEYWORDS
Decentralization, Programming Model, Norms, Protocols, Business Processes

ACM Reference Format:

1 INTERACTION-ORIENTED PROGRAMMING
Our research program, titled Interaction-Oriented Programming (IOP), concerns software abstractions for decentralized business processes, that is, systems that support interactions between multiple autonomous business principals. Autonomy refers to intelligent, flexible decision making. IOP stems from a single question.

How can we represent autonomy in software for business processes?

Current business process modeling technologies are typically based either on workflows (a centrally executed program) or choreographies (constraints on message ordering). Both rely on low-level (typically control flow) abstractions that are divorced from business meaning and are, therefore, incompatible with intelligent, decentralized decision making.

IOP unifies decentralized decision making with business process enactment. IOP has a single solution concept at its heart.

Representing autonomy in software requires representing the business meaning of communications.

E.g., in an e-business transaction between a buyer and a seller, an Offer message specifying an item and a price means the corresponding real-world offer (a domain object), which itself means a real-world commitment (a higher-level domain object) from the seller to the buyer for Delivery of the item if Payment of the price occurs. The meaning of a CancelOffer is to rescind some Offer; additionally, it means a commitment from the seller to Refund the buyer’s Payment if already made. When principals make decisions, they do so based on such meaning.

Communication meaning has a rich history in AI, marred though by early conceptual errors [8]. Our purpose with this demo is to show that the promising approach of social meaning has come of age; that it enables engineering business processes as loosely-coupled, decentralized multiagent systems. We demonstrate software for the following purposes.

2 DEMO: SPECIFYING BUSINESS CONTRACTS
We will demonstrate how a business processes may be specified in terms of declarative norms, which may be understood as elements of business contracts. We show how a traditional information store, e.g., a relational database may understood in terms of norms, thus supporting decision making [2, 3].

Listing 1: A commitment specification.

```
base events
quote(S, B, ID, item, price, t)
accept(S, B, ID, item, price, addr, t)
pay(S, B, ID, item, price, addr, t)
deliver(S, B, ID, addr, status, t)
refund(S, B, ID, amt, rAmt, t)

commitment PurchaseCom 5 to B
create quote
detach (accept and pay) within quote + 5d
  where amt >= price
  deliver within detach PurchaseCom + 10d

commitment Compensation 5 to B
create quote
detach violated PurchaseCom
discharge refund within violated PurchaseCom + 2d where rAmt >= amt
```

We demonstrate Cupid, a compiler that outputs SQL queries given norm specifications such as the one in Listing 1. The specification specifies the atomic business events (e.g., quote), each with
a key (the underlined attributes) for identifying its instances and a distinguished attribute t for timestamping purposes. The atomic events maps to relations in relational databases (the compiler in fact generates ‘Create table...’ statements.)

On top of the atomic events, commitments that capture business relationships may be specified. Listing 1 shows two commitments from S (seller) to B (buyer). PurchaseCom captures that S will make timely deliveries to B upon timely payment; Compensation captures that S will compensate B for violated instances of PurchaseCom.

The generated SQL queries enable principals to query databases in terms of commitment events, e.g., discharge, violation, expiry, and so on; in other words, in terms of key performance indicators (KPI). The queries run into hundreds of lines, illustrating that as simple and declarative as the commitments are, writing the relevant SQL queries by hand—the only alternative today—would be highly cumbersome and error-prone.

3 DEMO: BUSINESS CONTRACTS ON BLOCKCHAIN

Smart contracts as representations for business contracts are a nonstarter for several reasons, but two stand out. One, they can’t actually guarantee outcomes; two, they are anti-autonomy [11].

We demonstrate Hercule, software that interprets business contracts based on norms over blockchains [6]. Inspired from Cupid, Hercule enables laying out norms-based contracts on Hyperledger Fabric [1] and tracking norm states on the blockchain. Hercule is adapted to document-oriented databases, specifically CouchDB, the underlying database of the Hyperledger Fabric blockchain.

Hercule demonstrates that you can deploy realistic business contracts on blockchain. Hercule contracts, in contrast to smart contracts, support flexible decision making, since they don’t update the blockchain themselves, being just queries. Yet, they enable tracking the states of the contracts, thereby supporting compliance monitoring and accountability processes.

4 DEMO: SPECIFYING BUSINESS PROTOCOLS

Enacting a Cupid or Hercule business contract requires a declarative business protocol that captures the relevant information causality and integrity constraints. We will demonstrate how a business contract may be enacted in a decentralized manner on the basis of information protocols [9]. Listing 2 shows a protocol over which the commitments in Listing 1 could be operationalized.

Listing 2: An information protocol.

```plaintext
Purchase \{
  role B, S
  parameter out ID, out item, out amt, out status

  S \rightarrow B: quote[out ID, out item, out price]
  B \rightarrow S: accept[in ID, in item, in price, out addr]
  B \rightarrow S: pay[in ID, in item, in price, out amt]
  S \rightarrow B: deliver[in ID, in addr, out status]
  S \rightarrow B: refund[in ID, in amt, out rAmnt, out status]
}
```

Business protocols may be erroneously specified. For example, they may be specified in such a way that the agents enacting the protocols may make inconsistent decisions. Such protocols would not be safe [10]. Alternatively, a protocol may be such that on some branch, a decision required for termination can never be made. Such protocols would not be live [10]. We demonstrate tools for efficiently verifying the liveness and safety of protocols, in addition to properties such as refinement (which captures whether a protocol can substitute for another) [5] and atomicity (which is the idea that composite protocols not have any unterminated constituent protocols) [4].

A significant challenge for workflow-based business processes is relating to the content of communications. We demonstrate how our approach unifies coordination with content and in that supports business meaning, including in terms of business contracts.

5 DEMO: DECISION-BASED PROGRAMMING

In a business process, each communication represents a principal’s decision. We will show how to implement a principal’s software, that is, its agent in accordance with its own decision making policies [7]. We will demonstrate flexibility in decision making that is not possible with alternative technologies, e.g., workflow-based.

Specifically, we introduce a decision-oriented programming model in which one implements an agent by writing decision makers. The idea is that in any state, an agent can make a set of decisions. A decision maker picks some of those potential decisions, fleshes them out with the missing information by applying some internal business logic and communicates them via messages. Our programming model guarantees compliance and supports automatic correlation of decisions, multiprotocol decision making, and atomically making composite decisions that consists of several decisions-as-messages, among other things. Additionally, agents are fully asynchronous and operate purely on the basis of information and meaning rather than message ordering, as is commonplace in alternative software implementations of business processes. This enables our agents suitable to the IoT and they can be essentially be deployed as loosely-coupled microservices.

6 RELATED SOFTWARE

Cupid is available at https://github.com/akchopr/Cupid/.

All the other software, along with the relevant documentation is available at https://gitlab.com/masr/bspl/.

Attendees can pick the demos they are interested in.

ACKNOWLEDGMENTS

We thank the EPSRC (grant EP/N027965/1, Turtles) and the US National Science Foundation (grant IIS-1908374) for partial support.
